About Emerald www.emeraldinsight.com

Emerald is a global publisher linking research and practice to the benefit of society. The company manages a portfolio of more than 290 journals and over 2,350 books and book series volumes, as well as providing an extensive range of online products and additional customer resources and services.

Emerald is both COUNTER 4 and TRANSFER compliant. The organization is a partner of the Committee on Publication Ethics (COPE) and also works with Portico and the LOCKSS initiative for digital archive preservation.

Abstract

Purpose – The purpose of this paper is to study the development of research in computer science in 15 Eastern European countries following the breaching of the Berlin Wall in 1989.

Design/methodology/approach – The authors conducted a bibliometric analysis of 82,121 computer science publications indexed in the Web of Science database and investigated publication, citation, and collaboration patterns of the individual countries.

Findings – Poland has been the most productive country, followed by Russia, the Czech Republic, Romania, Hungary, and Slovenia. Publication rates have increased substantially over the period, but this has not been accompanied by a corresponding increase in the quality of the publications. Hungary and Slovenia are the most influential countries in terms of citations per paper. Artificial Intelligence is the most frequently occurring computer science subject category, with Interdisciplinary Applications the category with the greatest impact. USA, Germany, UK, France, and Canada are the most frequently collaborating western nations, and papers published in collaboration with US authors accrue the most citations.

Originality/value – This is the first ever bibliometric study of the whole post-communist Eastern European computer science research as indexed in the Web of Science.

Keywords Analysis, Web of Science, Eastern Europe, Computer science, Bibliometrics

Paper type Research paper

1. Introduction

The breaching of the Berlin Wall in 1989 was perhaps the most significant event in the break-up of the former USSR's domination of Eastern Europe. In the 25 years since then the Communist Block countries, both those already in existence (e.g. Hungary and Poland) and those arising from the subsequent break-up of the USSR (e.g. Belarus, Moldova, Ukraine and the Central Asia and South Caucasian states) have gone their separate ways socially, economically, and scientifically. In this paper, we present a bibliometric study of the development of computer science in 15 of these countries over this period.

There have already been several bibliometric studies of scientific developments in the former Communist Block (hereafter FCB) countries during this period. Thus, Karamourzov (2012) analysed development trends in the Commonwealth of Independent States and demonstrated the large, and in some cases, near catastrophic, reductions in scientific activity that have taken place. Kozak *et al.* (2014) showed that the break-up of

This work was supported by the European Regional Development Fund (ERDF), project "NTIS – New Technologies for Information Society", European Centre of Excellence, CZ.1.05/1.1.00/02.0090 and in part by the Ministry of Education of the Czech Republic under grant MSMT MOBILITY 7AMB14SK090.

the Block did not result in significant increase in publication counts or in academic collaborations with international researchers. Radosevic and Yoruk (2014) compared the science and social science capabilities of the countries of Central and Eastern Europe with those of the long-established members of the European Union. Allik (2013) contrasted the very different approaches to research excellence that have been taken by the three Baltic states (Estonia, Latvia, and Lithuania), Popovic *et al.* (2012) and Ivanovic and Ho (2014) discussed the improving quality of Serbian academic research, and Vanecek (2008) compared bibliometric data for the Czech Republic with six other EU countries. There have also been many published bibliometric studies of computer science, these involving either a comparison of multiple countries (e.g. Fiala, 2012; Guan and Ma, 2004; Ma *et al.*, 2008) or a focus on a specific country, e.g., Brazil (Arruda *et al.*, 2009), China (Xie and Willett, 2013), India (Gupta *et al.*, 2011), and Malaysia (Bakri and Willett, 2011). However, we are not aware of any such studies of computer science that focus on the FCB countries and the work reported here hence fills a niche in the literature. The next section summarizes the methods used, and we then discuss FCB publications, citations to those publications, the nature and extent of international collaborations involving these countries, and similarities between their individual research profiles.

2. Data and methods

The study is based on the Science Citation Index Expanded and the Conference Proceedings Citation Index – Science databases in the Thomson-Reuters Web of Science system. A search was carried out in early 2014 for journal articles, proceedings papers, or reviews published in the period 1989-2014 in the Research Area Computer Science, and then noting those FCB countries that had at least 1,000 publications that met these search criteria. In order of decreasing productivity these countries were: Poland, Russia, Czech Republic (shortened to Czech in some places of the text below), Romania, Hungary, Slovenia, Slovakia, Ukraine, Croatia, Bulgaria, Lithuania, Serbia, Yugoslavia, Latvia, and Estonia. Yugoslavia has been included in the list as meeting the publications threshold; however it should be noted that the last of its publications was in 2006, by which time the country had ceased to exist.

In addition to the countries above, searches were also carried out for the publications of the three South Caucasian states which lie on the boundary between Europe and Asia (i.e. Armenia, Azerbaijan, and Georgia), of four Balkan states (Albania, Macedonia, Montenegro, and Bosnia), of Moldova and Belarus, and of two other countries – the Soviet Union and Czechoslovakia – that are now defunct. None of these countries, however, had reached the minimal threshold of 1,000 publications and they were thus excluded from further analysis. (The first FCB country below the threshold was Belarus with 784 publications.) This study concentrates on Eastern Europe, and the Central Asian republics (e.g. Kazakhstan) were hence not considered at all. In total, the 26 countries inspected produced 82,121 publications; the 15 countries chosen for further analysis were responsible for more than 95 per cent of these publications. The full Web of Science publication records for the 15 countries were downloaded in March 2014 and saved as plain text files that were then subsequently imported into a relational database for the analyses that are described below. In this context it is relevant to note that, of course, the 2014 publication data are far from being complete and the 2013 publication data are, most probably, incomplete too due to indexation delays in the Web of Science database. However, we decided to retain these years in our analysis because 2014 marks the significant 25th anniversary of the fall of the Iron Curtain.

3. Results and discussion

3.1 Publications

In the period 1989-2014, the 15 countries considered here (and the 11 others with a negligible research output) produced a total of 82,121 computer science publications as detailed in Table I, which lists for each country the numbers of publications (*P*), the numbers of citations (*C*), the mean number of citations per publication (*CPP*), and the normalized *CPP* ratio (*NCPPR*). It will be seen that Poland is by far the most productive country, followed by Russia, the Czech Republic, Romania, Hungary, and Slovenia. That said, in looking at the figures in the table, account should be taken of how long the individual countries have been in existence. For example, three of the top-ranked countries – Poland, Romania and Hungary – existed in 1989 and have thus been able to produce publications and collect citations throughout the entire period under review; the only other countries with publications as early as 1989 were Bulgaria and Yugoslavia (which had changed its constitution during this period and which, as noted above, had ceased to exist by the end of the period under review). Since older publications have more time to attract citations, the unequal lengths of existence of the individual countries are reflected in *NCPPR* by averaging the yearly citations per paper divided by the mean number of citations per paper for all papers published in the same year.

The overall distribution of publications across all 15 countries is shown in Figure 1. Starting with just 457 publications in 1989, the general trend is for a steady increase until 2008-2009 when there were more than 7,000 publications, this being followed by substantial drops in 2010 (22 per cent) and in 2011 (a further 17 per cent) before an apparent levelling-off in 2012; the totals for 2013 and 2014 are incomplete since the data was collected in early 2014. Our assumption is that the most obvious reason for the marked drop-off is the world economic crisis, which started in 2008 and which might be expected to affect the subsequent volume of research and the consequent publications within a year or two of that happening. A comparable drop-off after 2009 is seen if all computer science research around the whole world is considered (rather than in just the FCB countries as here). One of the reviewers of this paper was interested in the exact development of all computer science production and so we added a second data series

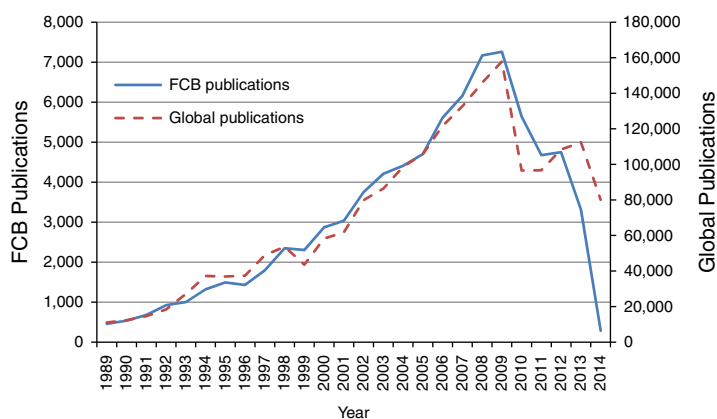

Figure 1. Distribution of FCB countries' publications and of global publications

with the publication counts of all computer science papers from the whole world (the dashed line). We can see that the trend is quite similar to our data under study even if they were collected more than a year earlier (March 2014 vs May 2015). However, the overall trend in computer science cannot be the only reason for the variations of FCB countries observed in Figure 1. Figure 2 shows the productivity curves for the six most productive countries, and it will be seen that the drop-off occurred in different countries at different times, presumably as a result of local circumstances. For example, in Hungary the drop-off occurred in 2007, which we ascribe to the worsening financial situation in the early years of the century causing the country's government to implement a strict austerity programme after the 2006 elections.

Thus far, the 82,121 publications have been considered as a whole. The publications for each country were then sub-divided into the seven Web of Science computer science subject categories: Artificial Intelligence, Cybernetics, Hardware and Architecture, Information Systems, Interdisciplinary Applications, Software Engineering and Theory and Methods (note that some publications have been assigned to multiple categories).

Figure 2. Distribution of the six most productive FCB countries' publications

The sub-divisions are detailed in Table II, where it will be seen that by far the most popular categories are Artificial Intelligence and Theory and Methods. Breaking down these totals by country enables the identification of national areas of particular expertise. For example, Artificial Intelligence figures prominently in the research profiles of Poland and Latvia, with each having almost 40 per cent of their publications devoted to this subject area; conversely, this category is under-represented in the profiles of Bulgaria, Yugoslavia, and Estonia. Cybernetics has the smallest total number of publications in Table II: it is studied most intensively in Russia (with 17 per cent of the country's total publications) and least intensively in Serbia (with less than 2 per cent of its publications). Hardware and Architecture has the next smallest number of publications in Table II: here the strongest focus is in Croatia and the weakest in Russia. Information Systems is the focus of no less than 52 per cent of all of Lithuania's computer science publications, whereas both Russia and Bulgaria have just 16 per cent of their publications in this category. The former high figure is probably due, in part at least, to the fact that the Web of Science journals *Informatics* and *Information Technology and Control* are both published in Lithuania and are home to 38 per cent of the Lithuanian publications in this category. Slovenia and Slovakia have the highest and lowest percentages, respectively, for publications in Interdisciplinary Applications; while Estonia and Croatia have the strongest, and Slovakia and Bulgaria the weakest, presence in Software Engineering. Theory and Methods is dominated by Russia, and least studied in Slovenia and Croatia; 35 per cent of the 5,255 Russian publications in this category appear in the *Journal of Computer and Systems Sciences International*, which is published in Russia. The inter-category variation is exemplified by Figure 3, which shows the research profiles across the seven Web of Science subject categories of the six most productive countries.

The titles of the 20 publications carrying the largest numbers of FCB outputs are listed in Table III, the two parts (a) and (b) corresponding to the periods 1989-2000 and 2001-2014, respectively. Each row contains a publication name, the number of FCB outputs in that period, and the impact factor (where this is available from the 2013 Journal Citation Reports database, with NA indicating that a value is not available). Eight of the journals are common to both tables, demonstrating (as one would probably expect) the long-term nature of many of the research interests. We have noted previously that high national publication rates in a particular journal can be related to the place of publication, and this is further evidenced by some of the data in Table III. For example, 33 per cent of the 2001-2014 FCB papers in *MATCH – Communications in Mathematical and in Computer Chemistry* came from Serbia, the country of publication; and a similar comment applies to 68 per cent of the 2001-2014 FCB publications in

Notes: *P*, number of publications; *C*, number of citations; *CPP*, mean number of citations per publication

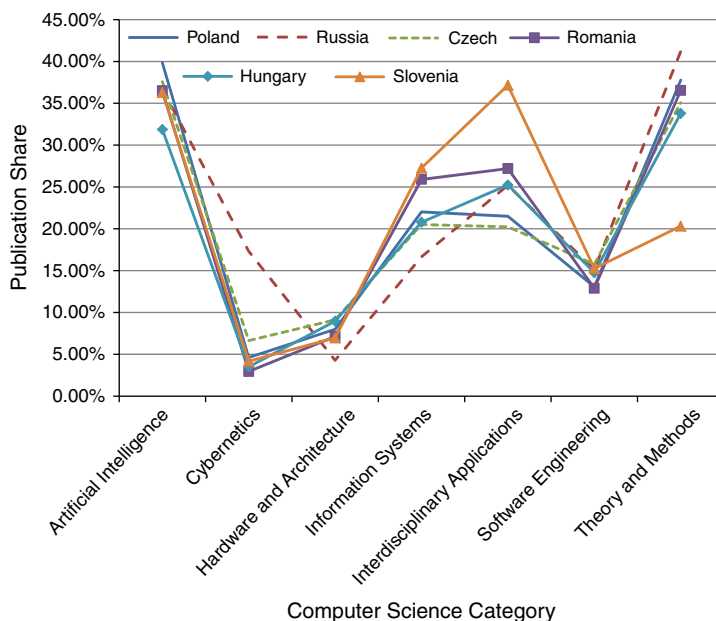

Figure 3. Research profiles of the six most productive FCB countries' publications

Fundamenta Informaticae that came from Poland; finally, no less than 87 per cent of the 1989-2014 FCB publications in *Kybernetika*, which is published in the Czech Republic, are listed as coming from there, from Slovakia or from Czechoslovakia.

One might hope that the substantial increases in publication rates evident in Figure 1 would have been accompanied by an increase in the quality of publication. However, a comparison of the mean impact factors, when averaged over those journals in Table III (a and b) for which data are available, shows that the mean has dropped from 1.455 for 1989-2000 to 1.302 for 2001-2014. Further analysis moreover suggests that the FCB countries publish only rarely in the most prestigious computer science journals (as denoted by their 2013 impact factors from the Journal Citation Reports database). For example, *ACM Transactions on Intelligent Systems and Technology* has the highest impact factor for the journals in both the Artificial Intelligence and Information Systems Web of Science categories; however, the 15 FCB countries contributed just 0.93 per cent of the publications in the journal using the search parameters described in the methods section (i.e. journal articles, proceedings papers or reviews; 1989-2014; and Science Citation Index Expanded or Conference Proceedings Citation Index – Science databases). Very low-percentage contributions are also observed for the most prestigious journals in two other categories: 0.40 per cent for *IEEE Wireless Communication* in Hardware and Architecture; and 0.64 per cent for *ACM Transactions on Graphics* in Software Engineering. Better results are obtained with *IEEE Transactions on Systems, Man and Cybernetics Part B-Cybernetics* in Cybernetics (2.39 per cent, where one-third of the FCB publications involve Witold Pedrycz (see Collaborations below)), and with *IEEE Transactions on Evolutionary Computation* in Theory and Methods (2.68 per cent). The highest percentage contribution of 6.11 per cent is obtained with *IEEE Transactions on Industrial Informatics* in the Interdisciplinary Applications category.

Notes: *P*, number of publications. Note that several of the journals in Table IIIa have changed their names: the *Journal of Chemical Information and Computer Sciences* is now the *Journal of Chemical Information Modelling*; *Computers and Artificial Intelligence* is now *Computing and Informatics*; and *Computers & Chemistry* is now *Computational Biology and Chemistry*

3.2 Citations

Turning now to the C and CPP values in Table I, it will be seen that there are considerable variations in the impact of the research conducted in the 15 countries, with Hungary and Yugoslavia (CPP value of 5.6) at one end of a spectrum that stretches down to Latvia (CPP value of 1.6) at the bottom. It is hence hardly surprising that when the CPP data are sub-divided by subject category, one obtains, as demonstrated in Figure 4, a more heterogeneous set of plots than is obtained from the publication data in Figure 3.

There are two ways of studying the relationship, if any, between the subject category and the citation impact. First, by computing the fraction of the total number of citations for a country that are received by the publications in a specific category; second, by computing the CPP values in each of the categories. The first approach helps to identify strongly (or weakly) cited categories for an individual country as compared to their impact in the other countries. For example, publications in Interdisciplinary Applications attract more than 60 per cent of all the citations for Croatia, Estonia, and Ukraine; while citations to publications in Cybernetics contribute less than 1 per cent of all the citations of Croatia, Estonia, and Serbia. The largest CPP values were obtained for Yugoslavia, Estonia and Hungary in Interdisciplinary Applications (values of 8.8, 8.4, and 7.9, respectively), Estonia in Information Systems (7.7), and Lithuania in Hardware and Architecture (7.1). It should be noted that this last high value is due in large part to an article by Avizienis *et al.* (2004): this had attracted 666 citations by March 2014, about ten times the number of citations for the second most cited Lithuanian publication.

The distribution of total citations to the papers published in the six most productive FCB countries in the individual years of the period under study is shown in Figure 5. Inspection of the figure reveals three well-marked peaks in the distributions: Hungary in 2001 with 3,442 citations; the Czech Republic in 2003 with 4,420 citations; and Slovenia in 2006 with 2,912 citations. These figures are clear outliers because the mean number of

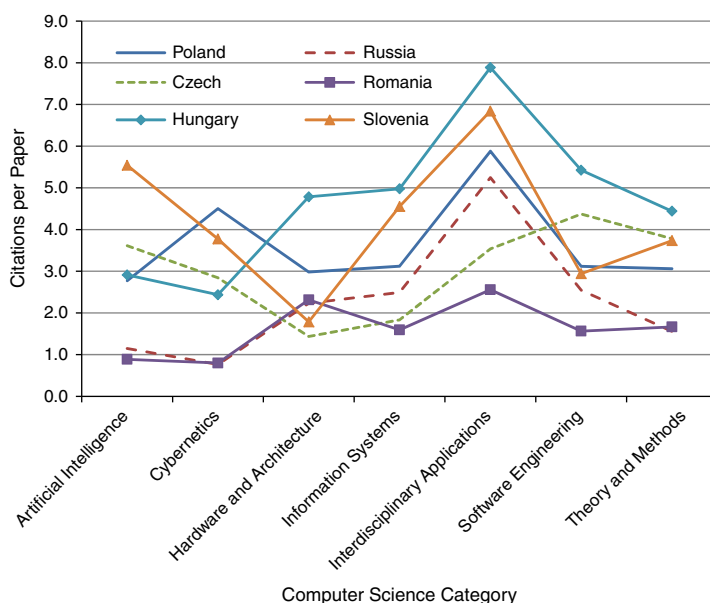

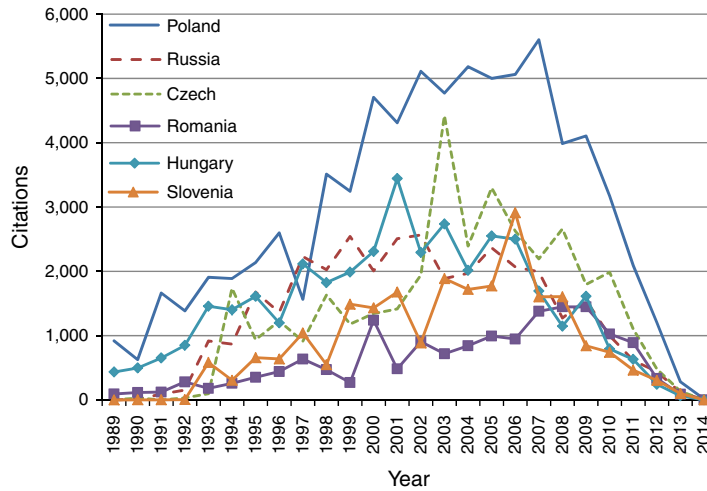

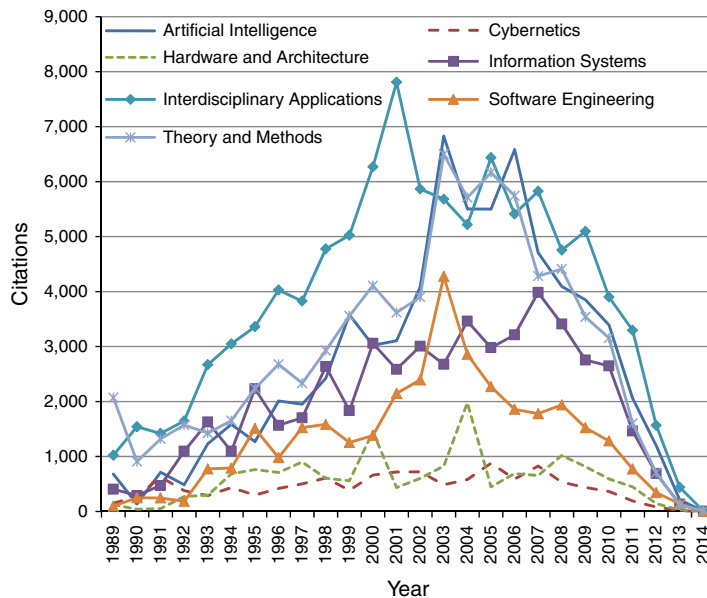

Figure 4. Research profiles of the six most productive FCB countries' citations per publication

Figure 5.
Citations to the
papers of the six
most productive FCB
countries published
in individual years

citations per year is 1,464 for Hungary, 1,368 for the Czech Republic, and 893 for Slovenia. The peaks are caused in large part by three heavily cited articles that make very substantial contributions to the total citations accrued in the respective years and countries: Tuszny and Simon (2001) with 884 citations, Zitova and Flusser (2003) with 1,737 citations, and Demsar (2006) with 1,176 citations. These are the fourth, first, and second most cited computer science articles produced in Eastern Europe from 1989 to 2014; the third most cited article is by Pudil *et al.* (1994) with 957 citations, causing another small Czech peak in 1994. Similarly, Figure 6 shows the distribution of citations to papers in the seven computer science categories over individual years, with well-marked

Figure 6.
Citations to the
papers of FCB
countries published
in various computer
science categories in
individual years

peaks being observed for Interdisciplinary Applications (2001 with 7,808 citations), Software Engineering (2003 with 4,277 citations), and Hardware and Architecture (2004 with 1,977 citations). All of these peaks are the result of articles noted above, namely, Tusnady and Simon (2001), Zitova and Flusser (2003), and Avizienis *et al.* (2004).

3.3 Collaborations

Many of the 82,121 publications involved international collaborations, with at least 1,000 publications involving each of the five following western countries (in order of decreasing number of collaborative publications): the USA, Germany, the UK, France, and Canada. The basic data for these collaborative publications are shown in Table IV.

The most striking part of Table IV is the right-hand column containing the *CPP* values, with even the smallest value here (9.7 for Canada) far exceeding even the largest values in Table I (5.6 for Hungary and for Yugoslavia) and with the value for the USA as high as 14.8. This differential level of citation has been noted previously by Teodorescu and Andrei (2011) who found that FCB publications involving international collaborators were typically cited about twice as much as those without such collaborations. The importance of international collaborations on the impact of research has been widely noted (Frenken *et al.*, 2009; Glänzel, 2001; Guerrero Bote *et al.*, 2013) and Table IV demonstrates that this is clearly the case here.

The extent of international collaborations involving the sets of five non-FCB and 15 FCB countries was studied by creating a 20×20 collaboration matrix, in which the I / J th element denoted the percentage of country I 's collaborative publications that involved collaborations with country J . Some of the resulting degrees of collaboration are quite strikingly asymmetric, most obviously for collaborations between the Czech Republic and Slovakia, where 7.2 per cent of the Slovak publications involved collaborations with Czech researchers, but where only 2.0 per cent of Czech publications involved Slovak researchers. In like vein, Croatia was much more dependent on Slovenia than vice versa; and the Ukraine was similarly more dependent on Russia, although it remains to be seen whether this will continue to be so given the current (2014) political unrest in the Ukraine. In Figure 7 there is a "heat map" of the collaboration matrix, only some aspects of which we discuss in the paper, and, for comparison, there is also a heat map of influence of these collaborations in terms of citations. For instance, Slovakia published 7.2 per cent of its research together with Czech, but this research accounts for 20.7 per cent of Slovakia's citations. Similarly, Ukraine's research with Russia (1.4 per cent) accounts for 15.3 per cent of its citations and Croatia's research with Slovenia (2.4 per cent) accounts for 10.6 per cent of Croatia's citations. In general, an international collaboration is rewarded by more impact, which is clearly shown in the heat maps. In particular, a collaboration with the USA is very advantageous for the FCB countries with the extreme case of Estonia and 44.2 per cent of its citations to the collaborative research with the

USA. By contrast, it is least advantageous for Serbia (only 6 per cent) but still better than with the other four western nations. The only country, for which it was better to collaborate with western countries different from the USA, is Ukraine whose publications with Germany and the UK had a greater impact (25.3 and 21.6 per cent vs 15.3 per cent).

Poland has the most extensive involvement with non-FCB researchers, with ca. 25 per cent of the joint publications for France, Germany, the UK, and the USA being with Poland. Canada is an extreme outlier here, with 51 per cent of its collaborative publications being with Poland. However inspection of the data reveals that almost one-half of these publications involve a single, highly productive scientist, Witold Pedrycz, who works in the areas of fuzzy sets and neurocomputing and who has concurrent affiliations with both the University of Edmonton and the Polish Academy of Sciences. After the USA, Germany has the most extensive range of collaborations, followed in turn by the UK, France, and Canada; the many German links may well arise in part from it being by far the geographically closest of these countries to the FCB. An alternative way of visualizing the collaboration relationships between countries is to generate graphs with nodes as countries and edges as collaborations, where the size of the nodes depends on the number of publications and the thickness of the (bidirectional) edges depends on the (relative) number of collaborations. We did produce such "collaboration diagrams", but due to the high number of edges they looked chaotic and showed little additional information so we content ourselves with presenting the heat maps.

Figure 8 shows the percentage of all publications in each of the years 1989-2014 that have involved a collaboration, either involving just FCB countries or involving both FCB and non-FCB countries. Two conclusions can be drawn from this figure: after a long period when the level of collaboration remained relatively constant, the last few years have seen a rapid increase in the percentage of collaboration-based publications; and collaborations that lie solely within the FCB are much less popular than those involving non-FCB countries, presumably because the latter can bring expertise and funding that is not available locally.

3.4 Cluster analysis

The discussion thus far has focused on the individual countries; in this section, we investigate potential relationships between them using the methods of cluster

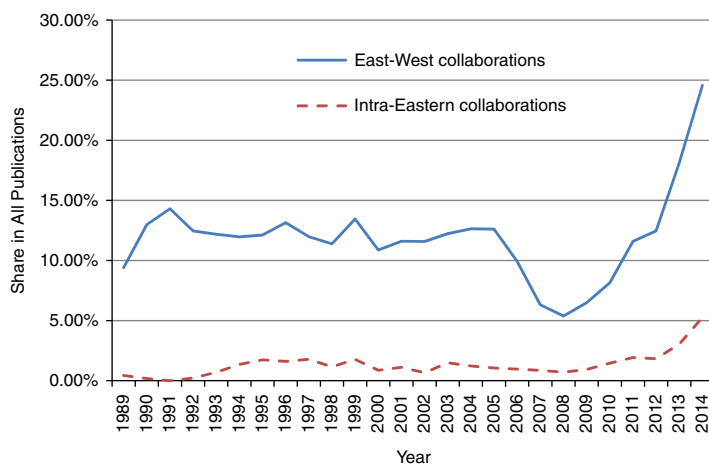

Figure 8.
Collaborations
between FCB and
non-FCB countries,
and just within the
FCB countries

analysis (Everitt *et al.*, 2011). This identifies groups, or clusters, of objects in a multi-dimensional space such that objects in the same cluster are close to each other and distant from those in other clusters. There are many different clustering methods available: here we have used the well-known Ward's (1963) hierarchical agglomerative method to cluster the 15 countries. The method results in a dendrogram, a tree structure in which each of the 15 clusters representing the individual countries are successively merged with other clusters to yield finally a single cluster containing all of the countries.

We have used first the research profiles as exemplified for six countries in Figure 3, i.e., the proportion of research publications in each of the seven Web of Science subject categories. The profiles here are clearly very similar to each other, and this is also the case for the remaining nine countries, with the result that the cluster analysis shows that all of the countries are grouped within a single cluster at a very small Euclidean distance. Similar comments apply if we consider each country's international collaborations with other countries, both FCB and non-FCB. Marked differences, however, are observed if we instead consider the citations per paper in each of the subject categories. The resulting dendrogram (Wessa, 2014) is shown in Figure 9, where the individual countries are represented by their top-level internet domains, e.g., RS (Republika Srpska) for Serbia. The dendrogram contains two well-separated clusters: one involving Croatia, Latvia, Romania, Russia, Serbia, and the Ukraine; and the other involving the remaining nine countries (Bulgaria, Czech, Estonia, Hungary, Lithuania, Poland, Slovakia, Slovenia, and Yugoslavia). It seems that there is an East-West split even within Eastern Europe regarding the citations per paper with the first cluster including more Easterly nations and the second cluster including more Westerly countries. Thus, the Czech Republic, Poland, Slovakia, Hungary, and Slovenia are geographically the most westerly countries in the region and their physical proximity appears to be reflected by being clustered together. Figure 9 also shows that the successor states (or the largest ones at least) resulting from the break-up of a country are still closely related to each other, e.g., the Czech Republic and Slovakia, Russia and the Ukraine, or Serbia and Croatia. Thus, the old relations between FCB countries obviously still persist in computer science.

Science subject
categories

4. Conclusions

Since 1989, the break-up of the Communist Block has resulted in substantial changes in the FCB countries, including changes in the nature of their scientific research. This paper has reported the first comparative study of the extent of these changes in academic computer science, using data from the Science Citation Index Expanded and the Conference Proceedings Citation Index – Science databases for the period 1989-2014. The main contributions of the study are as follows:

- we have analysed 82,121 journal articles and conference papers produced by researchers from 15 Eastern European countries in the period 1989-2014 and indexed in the Web of Science database;
- we studied the research production and impact of individual Eastern European countries over the years in the entire period under investigation as well as the production and impact of various computer science categories; and
- we conducted a cluster analysis of the countries with the aim of grouping them together on the basis of similarities in their publication, collaboration, and citation behaviour.

Based on the key results we achieved, we may conclude that the most productive Eastern European countries in computer science are Poland, Russia, Czech Republic, Romania, Hungary, and Slovenia. However, the publications of Hungary and Slovenia have the most impact in terms of citations per paper. But, in general, even though the total research production of the countries under study has increased substantially over the years, there is no similar effect regarding the impact of the publications produced. And, in addition, despite similar patterns in publication, collaboration, and citation behaviour of Eastern European countries, there is a visible East-West divide in this region with respect to the citations per paper in the individual computer science categories, with the western part nations' papers being generally more frequently cited.

An obvious limitation of the study is that it focuses on those countries that have at least 1,000 publications in the Web of Science database. One might argue that this threshold is too strict and that also other countries should have been included. Another problem is the instability of this part of the world, resulting in the appearance of new countries, the disappearance of old countries, and the existence of countries covering different territories during the period under study. These characteristics make some of the data difficult to measure and to interpret. Finally, much important research in computer science research is published in conference proceedings and these were poorly represented in the Web of Science for many years. Therefore, in our future work, we would like to focus also on other bibliographic databases and other scientific fields.

About the authors

Professor Dalibor Fiala Graduated from the University of West Bohemia (UWB) in Pilsen, Czech Republic in 2003, specialized in Software Engineering. He spent a semester at the Queen's University of Belfast, UK in 2001. He defended his doctoral thesis under joint supervision in 2007 and holds a PhD Degree from both the UWB and the Louis Pasteur University Strasbourg, France. From 2007 to 2009, Dalibor was a Software Engineer with Gefasoft AG, Munich, Germany. Currently, he is an Associate Professor at the Department of Computer Science and Engineering at the UWB. He is interested in web mining, information retrieval, and information science. Professor Dalibor Fiala is the corresponding author and can be contacted at: dalfia@kiv.zcu.cz

Professor Peter Willett, following a first Degree in Chemistry from Oxford, obtained MSc and PhD Degrees in Information Science from the Information School at the University of Sheffield. He joined the faculty of the School in 1979, and was awarded a Personal Chair in 1991 and a DSc in 1997. He has published over 500 papers on the processing of chemical, biological, and textual information, is in Who's Who, and has received many awards for his research, including: 1993 Skolnik Award of the American Chemical Society, 1997, Distinguished Lecturer Award of the New Jersey Chapter of the American Society for Information Science, 2001, Kent Award of the Institute of Information Scientists, 2002, Lynch Award of the Chemical Structure Association Trust, 2005, American Chemical Society Award for Computers in Chemical and Pharmaceutical Research, and 2010 American Chemical Society Patterson-Crane Award.
